Some mechanisms of the  $\text{Ca}^{2+}$ -induced  $\text{Ca}^{2+}$  release (CICR) are still a matter of debate, such as regulation of CICR. We have observed that in cardiac myocytes coherent activation of SR  $\text{Ca}^{2+}$  release induced refractoriness of CICR. It has been suggested that SR  $\text{Ca}^{2+}$  depletion and refilling may underlie refractoriness. Here we examined whether  $\beta$ -adrenergic stimulation could affect CICR. We used UV-laser flash photolysis of caged  $\text{Ca}^{2+}$  in combination with the whole-cell patch clamp technique to activate  $\text{Na}^+$ - $\text{Ca}^{2+}$  exchange currents in guinea pig ventricular myocytes. Pairs of UV-flashes were applied at various intervals to follow the time-course of recovery from refractoriness.  $\beta$ -adrenoreceptor stimulation affected SR  $\text{Ca}^{2+}$  content in two different ways. (1) Whereas the SR  $\text{Ca}^{2+}$  content was decreased when isoproterenol (Iso) treatment began after SR reloading, it was elevated if SR reloading was performed during Iso superfusion. (2)  $\beta$ -adrenergic stimulation (after SR reloading) resulted in a faster recovery of CICR from refractoriness. SR  $\text{Ca}^{2+}$  content and RyR phosphorylation both could lead to changes in  $\text{Ca}^{2+}$  sensitivity of CICR. Application of  $1\mu\text{M}$  Iso reduced the refractoriness, such that complete recovery of  $\text{Ca}^{2+}$  release could be observed earlier. We conclude that  $\beta$ -adrenergic stimulation may modulate global CICR refractoriness. This might result from acceleration of SR  $\text{Ca}^{2+}$  refilling or from a change of the  $\text{Ca}^{2+}$  sensitivity and/or gating kinetics of the RyRs.
