ABSTRACT

With the aim to develop compounds able to target multiple metabolic pathways and, thus, to lower the chances of drug resistance, we investigated the anti-trypanosomal activity and selectivity of a series of symmetric diglycosyl diselenides and disulfides. Of 18 compounds tested the fully acetylated forms of di-β-D-glucopyranosyl and di-β-D-galactopyranosyl diselenides (13 and 15, respectively) displayed strong growth inhibition against the bloodstream stage of African trypanosomes (EC₅₀ 0.54 μM for 13 and 1.49 μM for 15), although with rather low selectivity (SI < 10 assayed with murine macrophages). Nonacetylated versions of the same sugar diselenides proved to be, however, much less efficient or completely inactive to suppress trypanosome growth. Significantly, the galactosyl (15), and to a minor extent the glucosyl (13), derivative inhibited glucose catabolism but not its uptake. Both compounds induced redox unbalance in the pathogen. In vitro NMR analysis indicated that diglycosyl diselenides react with glutathione, under physiological conditions, via formation of selenenylsulfide bonds. Our results suggest that non-specific cellular targets as well as actors of the glucose and the redox metabolism of the parasite may be affected. These molecules are therefore promising leads for the development of novel multitarget antitrypanosomal agents.

1. Introduction

Chemotherapy represents, definitely, the first and most important line of defense to treat (sub)tropical diseases, like sleeping sickness or Chagas disease, caused by pathogenic trypanosomes. Molecules endowed with antitrypanosomal activity have been known since the beginning of the 20th century; almost all of them are still being used against human African trypanosomiasis (HAT; sleeping sickness). The third group of anti-HAT structures comprises aromatic bis(amidines) like pentamidine or DB289 (Thuita et al., 2015). Nifurtimox has long been in use for the treatment of Trypanosoma cruzi-induced Chagas disease but it has recently been found effective against sleeping sickness, particularly in combination with efomithine, itself an anti-HAT drug. Several molecules are being tested as new drug candidates; those which have entered Phase I clinical trials at least are reviewed by (Babokhov et al., 2013). The chemical structures of these trypanocidal molecules together with some others (see below) that did not reach yet the

http://dx.doi.org/10.1016/j.ijpddr.2017.08.001 2219-3207/© 2017 Published by Elsevier Ltd on behalf of Australian Society for Parasitology. This is an open access article under the CC BY-NC-ND license (http://creativecommons.org/licenses/by-nc-nd/4.0/).
clinical phase are shown in Fig. 1.

Almost all of the molecules in Fig. 1 contain aromatic/heteroaromatic ring systems and the common heteroatoms oxygen and nitrogen. The occurrence of other V/VI column heteroatoms are much sparser: arsenic in the three melarsen derivatives, sulfur in suramine, melarsoprol, nifurtimox and ebsulfur (Lu et al., 2013), and selenium in ebselen (José et al., 2013) only. Although carbohydrates, natural and synthetic derivatives alike, constitute one of the largest and most variegated group of biologically active compounds, these moieties occur only in some nucleoside derivatives with trypanocidal activity, such as Genzyme 644131/MDL-738 (Bacchi et al., 2009b) or cordycepin and analogs (Vodnala et al., 2013). Antitrypanosomal activities were recently recorded for aurano (see below), a gold-containing thiosugar (Ilari et al., 2012) and for some N-acyl-glucosamine derivatives (D’Antonio et al., 2015). Particularly, carbohydrate metabolism deserves attention as a potential target for the inhibition of trypanosomes because these pathogens depend on glucose as a preferred source of energy (Yorke et al., 1929; Bringaud et al., 2006) and as building block of several metabolic and structural macromolecules (Creek et al., 2015). Worth noting, glucose is the only source of energy for the bloodstream form of African trypanosomes.

Glycosyl disulfide derivatives, a novel class of carbohydrate structures (for a review see Szilágyi and Varela, 2006), gained importance recently as various biological activities were recorded for them such as binding to lectins (André et al., 2006; Murthy et al., 2009; Martin-Santamaría et al., 2011; André et al., 2015), enzyme inhibition (Kim et al., 2007) or anti-tumor activity (André et al., 2015). Moreover, some derivatives featuring monosaccharide sugar moieties attached to aromatic cores by disulfide linkages were found to inhibit the growth of T. cruzi at low μM range (Gutiérrez et al., 2013).

Encouraged by these results and by the fact that the bloodstream stage of the African trypanosomes is dependent on glucose consumption for survival we have set up a panel of carbohydrate structures exposing mono- or disaccharide moieties mounted on aromatic scaffolds by linker motifs containing sulfur or selenium atoms (1–12, Fig. 2). In a separate study these compounds were found to bind to lectins and have activity against tumor cell lines (Kaltner et al., 2017).

Organoselenium compounds and, particularly, symmetric dionary diselenides are known to have multiple biological activities and are relatively nontoxic to higher organisms (Shaaban et al., 2015). Some diaryl diselenide derivatives displayed anti-proliferative activity towards the intracellular form of Leishmania infantum (Plano et al., 2011; Baquedano et al., 2016). Some of them proved to inhibit trypanothione reductase (TR), the major reductase of trypanosomatids that contributes to redox homeostasis (Krauth-Siegel and Comini, 2008), suggesting that its mode of action involves interference with the intracellular redox balance. Worth noting, trypanothione metabolism has been involved in conferring trypanosomatids with resistance to different clinical drugs (Mäser et al., 2003; Maya et al., 2004; Walker et al., 2012; Alisford et al., 2012). To our knowledge, potential
antitrypanosome activities of sugar diselenides have not yet been investigated. We have therefore added compounds 13–18 (Fig. 3) to our testing panel. The rationale behind this approach was to target simultaneously two major metabolic pathways for these organisms: glycolysis and redox homeostasis with the major aim to increase compound 

**Fig. 2.** Chemical structures of sugar derivatives with aromatic cores tested against *Trypanosoma brucei*. 

**Fig. 3.** Chemical structures of diglycosyl diselenides tested against *Trypanosoma brucei*. 

Ac: O=CH₃
efficacy and lower the possibilities for emergence of drug resistance. The biological activity of the new derivatives was tested against the infective form of \textit{Trypanosoma brucei brucei}, causative agent of Nagana cattle disease and model organism of the sub-species pathogenic to humans. The potential mode of action of the most active derivatives was investigated.

2. Material and methods

2.1. Chemistry

Of the compounds listed in Fig. 2, 1–5 are disulfide glycoside analogs of those previously tested against \textit{T. cruzi} (Gutiérrez et al., 2013). The sugar moiety is either galactose (1, 2) or lactose (3–5) bound by β-glycosidic linkage to a benzene- (3) or a naphthalene (1, 2, 4 and 5) central core. 6 and 7 are analogs of 1 and 4, respectively, containing one sulfur atom less in the linker chains. 8–12 are analogous selenoglycosides with benzene- (8, 9) or naphthalene (10–12) aromatic cores. The chemical syntheses of 1–12 were recently published (Kaltner et al., 2017). Compounds 13 (Wagner and Nuhn, 1964), 15 (Kawai et al., 2005) and 17 (Ilyes et al., 2016) are diselenides of O- and/or N-acetylated glucose, galactose and glucosamine, respectively, whereas 14 (Wagner and Nuhn, 1964), 16 (André et al., 2015) and 18 (Boutureira et al., 2012) are the corresponding non-acetylated versions (Fig. 3).

2.2. Biology

2.2.1. Viability assays for trypanosomes and murine macrophages

Bloodstream \textit{T. b. brucei} (strain 427) cell line 449 expressing an ectopic copy of the redox biosensor hGrx-roGFP2 (Gutscher et al., 2008) was grown in HMI-9 medium supplemented with 10% (v/v) Fetal Bovine Serum Tetracycline-free (FBS; GIBCO®) in a humidified incubator with 5% CO₂ and at 37 °C. Phleomycin (0.2 μg/mL) and hygromycin (5 μg/mL) were added to select for the constitutive expression of the tetracycline repressor protein and for the hGrx-roGFP2 gene, respectively, whereas the expression of the last was induced by supplementing the medium with 1 μg/mL oxytetracycline for 24 h. Exponentially growing parasites were resuspended in fresh medium at a density of 5 × 10⁷ cells/mL, 200 μL of this cell suspension was seeded per well (96-well culture microplate). Next, 2 μL of the different compounds (final concentration of 5 μM) or DMSO (1% v/v) were added. After 24 h incubation, 100 μL from each well were transferred to a tube containing 200 μL of sterile PBS with glucose 1% (w/v). Prior to analysis by flow cytometry, propidium iodide (PI) was added at a final concentration of 2 μg/mL and used as a viability marker. Samples were analyzed with a C6Accuri flow cytometer (BD) using a 488 nm laser and the following filters \( \lambda_{\text{em}} = 530/40 \) nm and \( \lambda_{\text{ex}} = 613/30 \) nm for GFP and PI signal, respectively. The data were processed and analyzed with the C6Accuri software.

The murine macrophages (cell line J774) were cultivated in DMEM medium supplemented with 10% (v/v) FBS (GIBCO®), 10 U/mL penicillin and 10 μg/mL streptomycin, under a humidified 5% CO₂/95% air atmosphere at 37 °C. Cell viability was assessed using the WST-1 reagent.

For the selected compounds, \( EC_{50} \) was determined using a 7-point inhibition plot with each concentration tested in triplicate as described in (Maiwald et al., 2014) for \textit{T. brucei} and in (Demoro et al., 2012) for murine macrophages. \( EC_{50} \) values were obtained from dose/response curves fitted to a sigmoidal Hill equation (errors calculated using errors propagation) or extrapolated from non-linear fitting plots. The error is expressed as S.D and estimated as \( \sigma \) (n = 1). For all assays, cell viability was calculated as follows: viability (\%) = 100 x (number of cells for compound \( Y \) at concentration \( X \)) / (number of cells in the DMSO-treated control).

2.2.2. Assays involving \textit{T. brucei} redox reporter cell line

Bloodstream \textit{T. b. brucei} expressing the redox biosensor hGrx-roGFP2 was grown as described above. Two million parasites/mL were seeded per well in a 24-well plate and incubated (5% CO₂ and 37 °C) with 0.54 μM 13, 1.49 μM 15, 25 μM menadione, 78 mM suramin or 1% v/v DMSO for 4 h. Next, 100 μL from each well were transferred to a tube containing 200 μL of sterile PBS with glucose 1% (w/v). For each condition tested, a second sample was incubated with 1 mM DTT for 15 min prior to analysis by flow cytometry. PI was added at a final concentration of 2 μg/mL. All samples were analyzed with a C6Accuri flow cytometer (BD) as described above. GFP fluorescence (filter \( \lambda_{\text{em}} = 530/40 \) nm) was measured only for viable cells (PI negative). The data were processed and analyzed with the C6Accuri software. Samples were analyzed by triplicate and the error is expressed as S.D.

2.2.3. \textit{In vitro} assays with recombinant redox biosensor

Recombinant hGrx-roGFP2 was expressed with an N-terminal His-tag from Escherichia coli strain BL21 (DE3) grown in TB medium supplemented with ampicillin. At an optical density (600 nm) of 0.8, IPTG (0.5 mM) was added to the culture and incubation resumed for 16 h at 20 °C. Cells were then harvested by centrifugation at 5000 g for 20 min at 4 °C and the pellet resuspended in Buffer A (50 mM sodium phosphate pH 8.0, 300 mM NaCl with protease inhibitors and lysozyme). Cells were further lysed by three cycles of sonication (45% power, 2 s pulse on/off, for 1 min) and debris removed by centrifugation at 16,000 g for 1 h at 4 °C. Protein purification was done using a 1 mL HisTrap column (GE Healthcare) pre-equilibrated with Buffer A. hGrx-roGFP2 was eluted by a step gradient from 0 to 500 mM imidazole. The purity of recombinant hGrx-roGFP2 was of 95% as judged by Coomassie-stained SDS-PAGE.

For the redox assays, hGrx-roGFP2 was pre-reduced with DTT 20 mM in PBS containing 1 mM EDTA for 1 h at room temperature. The excess of reducing agent was removed by gel filtration on a Sephadex G25 (PD10 column, GE-Healthcare) equilibrated with PBS (pH 7.4) 1 mM EDTA. Protein concentration was measured at 280 nm, where \( \varepsilon_{280} = 23.290 \) M⁻¹ cm⁻¹ for hGrx-roGFP2.

The reduced biosensor (1 μM) was treated with 13 or 15 at their respective \( EC_{50} \) concentrations for 1 min and 1 h at room temperature, and then the fluorescence spectra at \( \lambda_{\text{ex}} = 380–510 \) nm were recorded on a Cary Eclipse equipment. Controls included incubation of the biosensor with 0.2 mM glutathione disulfide (GSSG), 1 mM DTT or glutathione (GSH) added at equimolar concentration with respect to the compound tested.

2.2.4. Glucose measurement

Bloodstream \textit{T. b. brucei} grown as described above were plated at 5.3–5.8 × 10⁶ parasites/mL per well in a 24-well plate and added of 0.54 μM 13, 1.49 μM 15, 78 mM suramin, 5 μM ebselen, 0.31 μM tri-thiazol (compound 10b from Franco et al., 2017) or 1% v/v DMSO. After 4 h incubation, viable parasites were quantified by light microscopy counting on a Neubauer chamber, then centrifuged at 2000 g for 10 min at room temperature. The supernatant was collected and glucose concentration was measured as described below.

Inhibition of glucose uptake was studied using a modified method from that described in (Seyfang and Duszenko, 1991). Bloodstream parasites in mid exponential growth phase were centrifuged at 2000 g for 10 min at 20 °C, washed with cold PBS 1X and resuspended at a final density of 6.1 × 10⁶ cells/mL in cold and fresh complete culture medium. Parasites were kept at 4 °C for 5 min, then incubated for 30 min at 37 °C with DMSO 1% (v/v) or the
following compounds added at 5X their EC$_{50}$: phloretin (500 µM), NFX (50 µM), 13 (2.7 µM) or 15 (7.45 µM). The experiment was stopped by boiling the samples for 5 min in a water bath. Cell debris were pelleted by centrifugation at 13000g for 10 min at 4 °C and glucose concentration was determined in the supernatant using a Bioprofile Basic 2 analyzer (Nova Biomedicals).

For both experiments, the samples were analyzed by triplicate and the error is expressed as S.D.

2.3. NMR spectroscopy

NMR samples for the $^1$H,$^1$H-NOESEY, $^1$H,$^13$C-HSQC and the $^1$H,$^{57}$Se-CPMG-HSQMBC (Williamson et al., 2000; Kover et al., 2006) correlation measurements contained ca. 25 mM diselenide derivatives 13 or 15 with three-to-four times excess of glutathione in a solvent consisting of 1:1 DMSO-$d_6$: phosphate buffer (100 mM in D$_2$O or H$_2$O: D$_2$O 9:1, pH 7.0). NMR experiments were performed at 298 K (NOESEY, $^1$H,$^13$C-HSQC) and at 313 K (HSQMCB), respectively, on a Bruker Avance II NMR spectrometer operating at 500.13 MHz for $^1$H equipped with a 5 mm inverse BBI-Z probe. The $^1$H resonances were assigned using standard homonuclear and heteronuclear correlation experiments. $^1$H,$^1$H-NOESY spectra were recorded using a mixing time of 200 ms and with 32 scans per $t_1$ increment. $^1$H,$^{57}$Se CPMG-HSQMBC correlation experiments were performed using a heteronuclear long-range coupling evolution time of 35 ms. The number of scans per $t_1$ increment varied between 320 and 640 depending on the concentration/solubility of the reaction product.

3. Results and discussion

3.1. Biological evaluation

The anti-trypanosomal activity of the symmetric diglycosyl diselenides and disulfides (compounds 1–18) was tested against the bloodstream stage of T. b. brucei, including nifurtimox (NFX) as control drug. Added at a concentration of 5 µM, only a subset of disaccharides harboring a diselenide bond and lacking an aromatic linker (compounds 13, 14, 15 and 17) displayed medium to strong anti-proliferative activity (37–97% growth inhibition, Table 1). Interestingly, acetylation of the sugar hydroxyl groups (in 13, 15 and 17) appears to be an important determinant of biological activity. In fact, the corresponding non-acetylated derivatives displayed lower (e.g., 43% for 14 compared to 97% for 13) to null (compare 15 vs. 16 and 17 vs. 18) growth inhibition.

Of all the molecules tested, 13 and 15 emerged as the most potent derivatives with EC$_{50}$ of 0.54 and 1.49 µM (Fig. 4A), respectively, followed by 14 and 17 with EC$_{50}$ of 5 µM (Table 1), all of them exceeding the activity of the control drug nifurtimox (EC$_{50}$ of 10 µM, under our assay conditions). The selectivity index of the most active compounds determined against murine macrophages was of 9.1 for 13 and 4.6 for 15 (Fig. 4B), these values being close to that of nifurtimox (SI – 10).

3.2. Potential mode of action of diglycosyl diselenides

The chemical nature of the disaccharide diselenides suggests that their anti-trypanosomal activity may be a consequence of some interference with the glucose- and/or redox metabolism of the parasite. In order to infer the potential mode of action of the most active compounds, namely 13 and 15, we first investigated the remaining level of glucose in the culture supernatant of parasites treated for 4 h with 13, 15, the antitrypanosomal drug suramin (a compound with multi-target activity; Willson et al., 1993), ebselen (an inhibitor of hexokinase 1 and trypanothione reductase from T. brucei; Joice et al., 2013; Lu et al., 2013) and a tri-thiazol that affects the integrity of the parasite lysosome (Franco et al., 2017). All compounds were tested at their corresponding EC$_{50}$ or with the vehicle alone (1% v/v DMSO) (Fig. 5A–D). Under these experimental conditions only the tri-thiazol and ebselen displayed some anti-proliferative activity with respect to the DMSO control, albeit not statistically significant. After 4 h incubation, the content of residual glucose in the medium supernatant was almost halved for all cultures with respect to the initial content (>5 g/L, Fig. 5A and C). However, comparison of the rate of glucose consumption ($\dot{v}$ = g/L glucose consumed per million parasites in 1 h) showed that parasites treated with 15 ($\dot{v}$ = 0.996) or with suramin ($\dot{v}$ = 0.141) presented a significantly lower capacity (<30%) to metabolize glucose compared to the control condition ($\dot{v}$ = 0.478 for DMSO) (Fig. 5B). Although compound 13 reduced nearly 10% glucose consumption ($\dot{v}$ = 0.341) vs. DMSO, this difference was not statistically significant. Under similar experimental conditions, the hexokinase 1 inhibitor ebselen ($\dot{v}$ = 0.184), but not a highly cytotoxic and non-mechanistically related tri-thiazol ($\dot{v}$ = 0.764), reduced by 44% glucose consumption compared to the vehicle ($\dot{v}$ = 0.332) (Fig. 5D).

An additional experiment was conducted to address whether the metabolic phenotype induced by compounds 13 and 15 in bloodstream trypanosomes involves the inhibition of glucose uptake. Measurement of glucose level in the culture medium upon a short exposure (30 min) of parasites to the diglycosyl diselenides added to 5X their EC$_{50}$ did not reveal differences in glucose uptake compared to vehicle treated cells (Fig. 5E). A similar outcome was obtained for nifurtimox (50 µM), a compound that does not directly affect glucose uptake but impair redox homeostasis (Hall and Wilkinson, 2012; Alsford et al., 2012) whereas phloretin (500 µM), a known competitive inhibitor of hexose transport in T. brucei (Segyf and Duszenko, 1991), reduced glucose uptake by 63% (Fig. 5E). Taken together, our data show that at low micromolar concentrations the diglycosyl diselenides do not interfere with glucose uptake and that the galactosyl derivative 15 affects significantly glucose catabolism.

Interestingly, while 15 exerted a higher depletion of glucose

* a Cell viability was assessed by flow cytometry and is expressed as % survival ± standard deviation (n = 3) relative to non-treated parasites.

T. brucei: Joice et al., 2013; Lu et al., 2013 and a tri-thiazol that affects the integrity of the parasite lysosome (Franco et al., 2017). All compounds were tested at their corresponding EC$_{50}$ or with the vehicle alone (1% v/v DMSO) (Fig. 5A–D). Under these experimental conditions only the tri-thiazol and ebselen displayed some anti-proliferative activity with respect to the DMSO control, albeit not statistically significant. After 4 h incubation, the content of residual glucose in the medium supernatant was almost halved for all cultures with respect to the initial content (>5 g/L, Fig. 5A and C). However, comparison of the rate of glucose consumption ($\dot{v}$ = g/L glucose consumed per million parasites in 1 h) showed that parasites treated with 15 ($\dot{v}$ = 0.996) or with suramin ($\dot{v}$ = 0.141) presented a significantly lower capacity (<30%) to metabolize glucose compared to the control condition ($\dot{v}$ = 0.478 for DMSO) (Fig. 5B). Although compound 13 reduced nearly 10% glucose consumption ($\dot{v}$ = 0.341) vs. DMSO, this difference was not statistically significant. Under similar experimental conditions, the hexokinase 1 inhibitor ebselen ($\dot{v}$ = 0.184), but not a highly cytotoxic and non-mechanistically related tri-thiazol ($\dot{v}$ = 0.764), reduced by 44% glucose consumption compared to the vehicle ($\dot{v}$ = 0.332) (Fig. 5D).
Fig. 4. Dose-response curves for the most active diglycosyl diselenides. A) Bloodstream T. b. brucei and B) murine macrophages (cell line J774) were treated with different concentrations of 13 and 15. After 24 h incubation, cell viability was assessed by flow cytometry (Accuri BD) using propidium iodide as exclusion dye. The data were fitted to the Hill equation with R² values > 0.96. The EC₅₀ against T. b. brucei is 0.54 ± 0.05 µM for 13 and 1.49 ± 0.01 µM for 15, contrasted to the values of 4.9 ± 0.45 µM for 13 and 6.9 ± 0.54 µM for 15 against macrophages.

Fig. 5. Glucose catabolism and uptake studies in bloodstream T. b. brucei. A) and C) Residual glucose and parasite proliferation. Cell density (black bars) and residual glucose in culture supernatant (white bars). The red and blue dotted lines depict the initial cell density (5.8 × 10⁶ cells/mL and 5.3 × 10⁶ cells/mL) and glucose concentration (5.5 g/L and 5.1 g/L) in the culture medium of the corresponding experiments. B) and D) Glucose consumption. Parasites were treated with vehicle (1% v/v DMSO), 13 (0.54 µM), 15 (1.49 µM), suramin (78 nM), ebselen (5 µM) and tri-thiazol (0.31 µM) for 4 h and glucose consumption (ϕ) is expressed as g/L glucose consumed per million cells in 1 h. E) Glucose uptake. Parasites were treated with vehicle (1% v/v DMSO), 13 (2.7 µM), 15 (7.45 µM), nifurtimox (50 µM) or the control drug phloretin (500 µM) for 30 min. All values are expressed as average ± SD (n = 3). Statistical analysis was performed applying One Way ANOVA test followed by Dunnet’s multiple comparisons posttest. ****, ** and * denote differences with p values < 0.0001, <0.01 and < 0.5, respectively, vs. DMSO control. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
consumption than 13, the last one produced a comparatively stronger cytotoxic effect on cells (Fig. 4A). Next we were interested to gain insight into a potential interference of the compounds with the cell redox homeostasis using parasites that express a fluorescent redox biosensor in their cytosol. The biosensor hGrx-roGFP2 allows quantifying the ratio of reduced and oxidized glutathione in a non-invasive manner (Gutscher et al. 2008). Though trypanosomes lack glutathione reductase, the redox state of glutathione is in equilibrium with that of trypanothione, the major redox cofactor of these parasites, via a class I glutaredoxin (Comini et al., 2013; Musunda et al., 2015). Thus, this tool provides a rationale measure of the overall intracellular redox state of the parasite. As shown in Fig. 6, bloodstream T. b. brucei treated with the diglycosyl diselenides at their EC50 for 4 h displayed a marked oxidation of the biosensor (30% for 13 and 25% for 15) that was only partially reverted upon 15 min incubation with the membrane permeable reducing agent dithiothreitol (DTT). As expected, treatment with the vehicle or suramin did not induce redox changes while the redox cycler drug menadione produced a significant oxidation (60%) of the biosensor that was fully reversible after exposure to 1 mM DTT for 15 min.

Despite hGrx-roGFP2 has been shown to be highly selective and sensitive (nM concentration) towards glutathione disulphide (GSSG) (Gutscher et al. 2008), the diselenides 13 and 15 may, in principle, act as direct oxidants of the cysteines present in the biosensor. This hypothesis was ruled out upon treatment of recombinant hGrx-roGFP2, purified from transformed bacteria, with 13 and 15 at their EC50. No changes in the fluorescence spectra of hGrx-roGFP2 were observed after 1 min or 1 h incubation with either of these compounds, while the biosensor was rapidly (≤1 min) oxidized by 200 nM GSSG and reduced following addition of 1 mM DTT. In addition, co-incubation of 13 or 15 with an equimolar concentration of glutathione for 1 h did not trigger redox changes in hGrx-roGFP2, suggesting that 13 or 15 are neither able to oxidize the low molecular weight thiol to its disulfide form (Fig. 7). The oxidative shift in the intracellular redox milieu of the parasite may well originate from a compromised supply of ATP to synthesize low molecular weight thiols (e.g. glutathione, trypanothione) that cannot counteract the endogenous metabolic demand for reducing power (Krauth-Siegel and Comini, 2008). Moreover, it was suggested that nucleophilic attack on the Se-Se bond in diaryl-diselenides by cysteine residues in proteins/enzymes, such as TR, might also influence redox balance via putative selenol derivatives (Font et al., 2015). However, the chemical nature of diglycosyl diselenides prompts us to hypothesize that they may also react directly with components of the redox metabolism, in particular with low molecular mass thiols.

To address this question, we performed NMR spectroscopic measurements with mixtures made up of the two most active diselenides (13 and 15) and excess glutathione under near physiological conditions. In the 1H NMR spectrum of 13 + glutathione a second set of resonances for the Cys-βCH2 protons (A, B) of glutathione appears (Fig. 8A), which indicates the formation of a new molecular species. 1H,77Se-heteronuclear correlation experiments (Williamson et al., 2000; Kovér et al., 2006; Boros and Kovér, 2011) performed with the above sample clearly revealed long-range couplings between the 77Se nucleus and the Cys-βCH2 protons (A, B) of glutathione (Fig. 8A). These results can be explained by the formation of a molecular species containing the sugar moiety attached to the cysteine residue of glutathione via a

**Fig. 6.** Intracellular redox changes induced by 13 and 15 on bloodstream T. b. brucei. Two million parasites were exposed to 0.54 µM 13, 1.49 µM 15, 78 nM suramin, 25 µM menadione, 1 mM DTT or left untreated (vehicle, 1% v/v DMSO) for 4 h (black bars) and then treated for 15 min with 1 mM DTT (grey bars). The values are expressed as percentage ±SD) reduction of the biosensor relative to the control condition with DMSO without added DTT (n = 3). Statistical analysis was performed applying One Way ANOVA test followed by Dunnet’s multiple comparisons posttest. ***, ** and * denote differences with p values < 0.001, <0.01 and < 0.5, respectively, vs DMSO control.

**Fig. 7.** Compounds 13 and 15 do not induce oxidation (to disulfide form) of the redox biosensor or glutathione in vitro. Fluorescence spectra of the recombinant redox biosensor (hGrx-roGFP2, 1 µM, green line) incubated with compound 13 (orange line) or 15 (blue line) at their EC50 values, and added or not of 0.2 µM oxidized glutathione (GSSG, red line) and 1 mM DTT (black line), or an equimolar concentration of reduced glutathione, dashed orange line or dashed blue for 13 or 15, respectively. Data obtained upon (A) immediate reaction (≤1 mm) and (B) 1 h incubation and expressed as relative fluorescence units, u.r.f., vs. excitation wavelength. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
Fig. 8. a) $^1$H,$^{77}$Se multiple-bond CPMG-HSQMBC correlation spectrum of a solution of 13 in 1:1 DMSO-$d_6$: phosphate buffer (100 mM in D$_2$O, pH 7.0) and glutathione in 1:4 M ratio reveals $^1$H,$^{77}$Se coupling connectivities between selenium and the cysteine $\beta$-protons (A, B) of glutathione. b) Structure of selenenylsulfide 20 highlighting crucial $^1$H,$^{77}$Se coupling connectivities. Shown above the 2D map is the $^1$H NMR spectrum with indications of the relevant protons in b. The $^{77}$Se spectrum (on the left of the 2D map) provides further confirmation for the structure of 20 via a distinctly different $^{77}$Se chemical shift with respect to that in 13 ($\delta_{\text{Se}}$ 483 ppm in 20 vs. 400 ppm in 13).
selenenylsulfide bond (20, Fig. 8b).

Similar results were obtained for the reactions of 15 with glutathione or with N-acetylcysteine indicating the formation of selenenylsulfides 19 and 22, respectively (Supplementary Figs. S1 and S2). Further support for the structure of 19 was obtained by 2D 1H,1H-NOESY (Supplementary Fig. S3) as well as by 1H,13C-correlated 2D HSQC spectra (Supplementary Fig. S4). At this point we got intrigued to inquire about the behavior of 16, the deacetylated form of 15, in the presence of glutathione in view of the fact that 16 was found to be practically inactive in the growth inhibition test (Table 1). The 1H,13C correlation experiment run under identical conditions indicated the formation of a selenenylsulfide derivative, 21 (Supplementary Fig. S5), in complete analogy to what has been observed for 15. This result shows that, while selenenylsulfide formation is likely to take place in these systems, such reactions alone cannot account for the striking difference in trypanosome inhibition efficiency (Table 1) between the acetylated (such as 15) and non-acetylated (such as 16) forms of diglycosyl deselenides. It is of note that the chemical synthesis of analogous glycosylselenenyl-glutathione derivatives has been reported using a similar protocol which has, furthermore, been found useful for the glycosylation of thiol groups in these molecules takes place under milder, quasi physiological conditions via formation of SeS-linkages between the reactants. The resulting selenenylsulfide derivatives may potentially act as inhibitors of enzymes in the glucose and redox metabolism of the parasites. The low selectivity of the most active compounds indicates that these molecules may share molecular targets in the pathogen and in the host as well. Nonetheless, the enhanced cytotoxic effect of the compounds towards parasites can be explained by the fact that glutathione concentration in trypanosomes is at least one to two-orders of magnitude lower than in mammalian cells and, additionally, due to the higher dependency of infective African trypanosomes on glucose catabolism for obtaining energy, reducing power and as precursor of several important macromolecules (Creek et al., 2015). Future studies should address the potential of selenosugar derivatives towards trypanosome inhibition as well as a quest for potential targets in the parasite and mammalian cells.
