1. Introduction

Glucose has a central role in the energy supply of the body. Blood glucose levels are controlled by the continuous interaction of two metabolic pathways: the glucose and the glycogen metabolism. Insufficient operation of this complex system – regulated by enzymes and hormones – results in altered, usually chronically elevated blood sugar levels. This syndrome is diabetes mellitus, a serious disease becoming one of the main contributors to worldwide mortality through its long term complications. The end of the 20th century has seen a dramatic increase in the number of patients diagnosed with diabetes worldwide. This disease afflicts approximately 6% of the adult population in the Western society.

Depending on whether patients secrete insulin or not, diabetes can be divided into two basic types: type I, or insulin-dependent diabetes mellitus (IDDM) and type II, or non-insulin-dependent diabetes mellitus (NIDDM) which represents ~90% of all diabetic cases.

Contrary to type I diabetes most of type II diabetics can synthesize and secrete insulin although not in sufficient quantities or insulin exerts no or only a late effect on stimulating glucose uptake by cells and on stimulating glycogen synthesis. NIDDM typically afflicts people over 40 and the symptoms develop more slowly. Patients require complex treatment that involves regular physical activity and dietary regulation besides the use of oral hypoglycemic agents.

Biological/biochemical backgrounds of diabetes formation are not known. Since all of its symptoms and complications originate from the altered, elevated blood glucose levels current treatments aim to maintain a constant, approximately normal blood glucose level. For type II diabetes several sorts of oral hypoglycemic drugs (sulfonylureas, biguanides, thiazolidinediones, acarbose) are in use for symptomatic treatments but they have several adverse side effects as well as the danger of causing hypoglycemia. Therefore other therapeutic concepts (among others novel insulin secretagogues, insulin sensitizers, glucagon receptor antagonists, inhibitors of hepatic glucose output, combination therapies) are intensively investigated, and a wholly nutritional therapy has been suggested, as well.

A newly investigated approach is the inhibition of glycogen phosphorylases (GP-s) which are the main regulatory enzymes of glucose production in the liver, in the muscles and in the brain.

At the beginning of my PhD studies glucopyranosylidene-spiro-hydantoin 20 and its thio derivative 21 were the most effective glucose analogue inhibitors of glycogen
phosphorylases. However, neither of them was available in larger quantities sufficient for biological investigations.

\[
\begin{align*}
20 & \quad X = O \quad \text{RMGP}b \quad K_i = 3.1 \ \mu\text{M} \\
21 & \quad X = S \quad \text{RMGP}b \quad K_i = 5.1 \ \mu\text{M}
\end{align*}
\]

(RMGPb: rabbit muscle glycogen phosphorylase b)

Taking the spiro-(thio)hydantoin s as lead structures the aim of my PhD research has been the development of glucose analogue inhibitors of glycogen phosphorylases:

– elaboration of a scalable synthetic sequence for the preparation of glucopyranosylidene-spiro-thiohydantoin.

– developing new intramolecular spirocyclisations to obtain novel glucopyranosylidene-spiro-heterocycles with potential GP inhibitory activity.

2. Methods

The macro- and micro methods of the modern preparative organic chemistry were used in my synthetic work.

Thin layer chromatography was applied to follow the reactions, to control the purity of compounds. Coloumn chromatography and crystallisation were used for the purification of the products. Melting point, elemental analysis, optical rotation determination, mass- and NMR spectroscopic methods were applied for the verification of the purity and the structures of the prepared substances.

3. New scientific results

3.1. Large scale synthesis of the glucopyranosylidene-spiro-thiohydantoin

On the basis of a procedure (Ősz et al. Bioorg. Med. Chem. Lett. 1999, 9, 1385-1390.) giving glucopyranosylidene-spiro-thiohydantoin 21 in a very poor yield (~2%) we have worked out a new method by which the overall yield for 21 has grown to 30%.
a.) By changing the acetyl protecting groups applied in the original synthesis to benzoyl the yield of the key intermediate glucopyranosyl-cyanide 105 increased from 11% to 58%, as well as the chromatographic separations were no longer needed. However, by the chromatographic purification of the mother liquor further 16-19% crop of 105 was obtained. This means that the formation of cyano-benzylidene derivative is not significant.

b.) NBS used earlier in the bromination reactions was changed to elemental bromine, hereby work-up of the reaction mixtures became more simple.
\[ \text{R = Ac}^* \]

\[ \text{R = Bz} \]

- for seven steps:
- \( \sim 30\% \)

It was shown, that carbon tetrachloride generally used in similar reactions was replaceable by the more available chloroform or dichloromethane and the radical brominations could be effected at lower temperature.

c.) The partial hydrolysis of the cyano groups in 105 and 106 was carried out with HBr in acetic acid, thus the corresponding benzoylated C-(β-D-glucopyranosyl)-formamides (107, 108) were obtained as crystalline crude products in high yields.

d.) Reaction of 108 with ammonium or potassium thiocyanate in nitromethane in the presence of elemental sulfur to suppress radical-mediated pathways under nitrogen atmosphere gave spiro-thiohydantoin 109 and hydroxy-amide 110. Compound 110 was also prepared independently from 108 by oxide-promoted hydrolysis in dimethylsulfoxide. Debenzoylation of 109 was accomplished by the Zemplén method in methanol to give inhibitor 21 in 92% yield.

e.) Thiohydantoin 21 was prepared in gram scale quantities by this new method allowing extended biological investigations with glycogen phosphorylases performed at the Department of Medicinal Chemistry of University of Debrecen. Compound 21 significantly lowered the enzyme activity in both in vitro and in vivo experiments and was shown to diminish blood sugar levels in vivo. These findings corroborate the concept of using glycogen phosphorylase inhibitors as a potential antihyperglycaemic agents.

3.2. Synthesis and photoreactions of N-acyl-N’-β-D-glucopyranosyl ureas

Radical reactions at the anomeric center of sugars show high regio- and stereoselectivity, that is why we have planned the synthesis of compounds similar to glucopyranosylidene-spiro-hydantion 20 in a photochemical way (Norrish type II reaction) according to the retrosynthetic scheme.

\[
\begin{align*}
\text{O} & \text{H} \quad \text{N} & \text{H} \quad \text{O} \\
\text{O} & \text{H} \quad \text{N} & \text{H} \quad \text{O} \\
\text{R} & \text{H} \quad \text{N} & \text{H} \quad \text{O} \\
\end{align*}
\]

a.) Protected N-acyl-N’-β-D-glucopyranosyl ureas (92, 93, 112-117), which could be convenient precursors for this photocyclisation, were prepared from acetylated glucopyranosyl azide 95 in two ways: by the acylation of glucopyranosyl urea (Route A) or via glucopyranosyl amine with acyl isocyanates (Route B).
b.) Photolyses of per-O-acetylated N-acetyl- (92) and N-benzyol-N'-β-D-glucopyranosyl ureas (93) were carried out under various conditions. These resulted in Norrish type I N-deacylation only, therefore, these molecules proved to be unsuitable for photocyclisation.

c.) The ureas were deprotected by classic Zemplén method or with KHSO₄ or ammonia in methanol to give 118-125, while 126 was obtained by Raney-Ni reduction of 120.

\[
\begin{align*}
92 & \quad R = \text{CH}_3 \quad 56\% \ (A) \\
93 & \quad R = \text{C}_6\text{H}_5 \quad 30\% \ (A) \\
112 & \quad R = 4\text{-NO}_2\text{-C}_6\text{H}_4 \quad 60\% \ (A) \\
 & \quad 65\% \ (B) \\
113 & \quad R = 3\text{-Cl-C}_6\text{H}_4 \quad 74\% \ (B)
\end{align*}
\]

\[
\begin{align*}
114 & \quad R = 4\text{-OAc-C}_6\text{H}_4 \quad 72\% \ (A) \\
 & \quad 20\% \ (B) \\
115 & \quad R = \text{1-naphthyl} \quad 73\% \ (A) \\
116 & \quad R = \text{2-naphthyl} \quad 29\% \ (A) \\
117 & \quad R = \text{2-indolyl} \quad 41\% \ (A)
\end{align*}
\]

\[
\begin{align*}
118 & \quad R = \text{CH}_3 \quad 370.5 \\
119 & \quad R = \text{C}_6\text{H}_4 \quad 4.6 \\
120 & \quad R = 4\text{-NO}_2\text{-C}_6\text{H}_4 \quad 3.0 \\
121 & \quad R = 3\text{-Cl-C}_6\text{H}_4 \quad 113.6 \\
122 & \quad R = 4\text{-OH-C}_6\text{H}_4 \quad 3.6 \\
123 & \quad R = \text{1-naphthyl} \quad 7.8 \\
124 & \quad R = \text{2-naphthyl} \quad 0.4 \\
125 & \quad R = \text{2-indolyl} \quad 8.0 \\
126 & \quad R = 4\text{-NH}_2\text{-C}_6\text{H}_4 \quad \text{IC}_{50} = 14
\end{align*}
\]
d.) These compounds were found to inhibit GP, and among them N-2-naphthoyl-N'-β-D-glucopyranosyl urea (124) has been the most effective with its nanomolar $K_i$ value, and is at present the best glucose analogue inhibitor of GP.

e.) Crystallographic studies have shown that some of these compounds bind also at the so-called new allosteric site of GP besides the catalytic site, which is a unique property among glucose derivatives. With the preparation of N-acyl-N'-β-D-glucopyranosyl ureas new leads have been discovered for the inhibition of GP.

3.3. Experiments towards the synthesis of glucopyranosylidene-spiro-1,2,4-oxadiazolines

New glucopyranosylidene-spiro-oxadiazolines were also targeted on the basis of kinetic and crystallographic results with the above molecules as well as some glucopyranosylidene-spiro-oxathiazoles which were found to be micromolar inhibitors of GP. This synthesis was planned by the photolysis of per-O-acetylated N-β-D-glucopyranosyl amidoximes under oxidative circumstances.

\[ \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{H} \quad \text{N} \quad \text{R} \quad \text{R}' \]

\[ \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{N}_3 \]

↑

\[ \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{H} \quad \text{N} \quad \text{R} \quad \text{R}' \]

a.) The unknown precursors were obtained by a modified Staudinger reaction from per-O-acetylated β-D-glucopyranosyl azide reacted first with trimethylphosphine and then with aryl hydroximinoynl chlorides.

\[ \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{AcO} \quad \text{N}_3 \quad \text{Me}_3\text{P}, \text{toluene} \quad \text{CH}_2\text{Cl}_2 \]

\[ 1. \text{R}' = \text{Ac}, \text{R} = \text{C}_6\text{H}_5 \quad 57\% \]

\[ 2. \text{R}' = \text{Ac}, \text{R} = 4-\text{NO}_2\text{-C}_6\text{H}_4 \quad 64\% \]

\[ \text{R}' = \text{Ac}, \text{R} = 4-\text{CN}\text{-C}_6\text{H}_4 \quad 59\% \]

\[ \text{R}' = \text{Ac}, \text{R} = 2\text{-naphthyl} \quad 6\% \]

\[ \text{R}' = \text{H}, \text{R} = 4\text{-NO}_2\text{-C}_6\text{H}_4 \]

\[ \text{R}' = \text{H}, \text{R} = 4\text{-CN}\text{-C}_6\text{H}_4 \]

b.) Photoreactions of acetylated N-β-D-glucopyranosyl 4-nitro-benzamidoxime 137 in the presence of NBS suggest the formation of the target spiro-oxadiazoline 143 in which the sugar ring is liable to open to form an aromatic 1,2,4-oxadiazol 145. The secondary alcohol can be oxidized to 146 under the reaction conditions. In conclusion the examined reaction is unsuitable for the preparation of the desired, likely unstable glucopyranosylidene-spiro-oxadiazoline. The deprotected derivatives 147 and 148 showed no inhibition of GP.
\[
\text{Ar} = p-C_6H_4-NO_2
\]

Amounts of NBS: 4 eq. 4x1 eq. 4 eq.
Power of the IR lamp: 60W 60W 375W
4. Possible applications of the results

A new, high yielding, simple synthesis of glucopyranosylidene-spiro-thiohydantoin 21 was developed starting from d-glucose to produce gram quantities of 21, thus in vitro and in vivo studies of this efficient GP inhibitor on hepatic glycogen metabolism have become possible.

Various N-acyl-N′-β-d-glucopyranosyl ureas (118-126), which can be regarded as “open chain” analogues of hydantoin 20, were also prepared. They proved to be very efficient inhibitors of GP, even the most active glucose analogue inhibitor known to date, the 2-naphthoyl derivative 124 has been found among them (K_i =0.4 µM). Thus they can be the new “lead structures” of further investigations.

Possibilities of a photochemical synthesis of new glucopyranosylidene-spiro-oxadiazolines from per-O-acetylated N-β-d-glucopyranosyl amidoximes were investigated. According to our findings the target oxadiazolines are likely unstable and cannot be prepared by the method examined.
